The Series in Pandas is a onedimensional array that uses the Series()

method to create a Series, but it also uses

different built-in attributes and methods

for basic functionalities. In this lesson, let us see such attributes and methods i Men

Python Pandas for Series:

- dtype: Return the dtype. ndim: Return the Number of
- dimensions size: Return the number of elements.
- name: Return the name of the Series.

hasnans: Returns True if NaNs are in

- the series. index: The index of the series
- head(): Return the first n rows.
- tail(): Return the last n rows.
- info(): Display the Summary of the series

Let us understand them one by one:

dtype

The **pandas.series.dtype** is used to return the datatype of the Series.

ttribute in O. Dython Pandas:

The **pandas.series.dtype** is used to return the datatype of the Series. Let us now see an example to implement

10:44 | 1.1KB/s ම්

dtype

Series:

0

10

20

اله اله

the type attribute in Q <u>Python</u> Pandas: Men

import pandas as pd # Data to be stored in the Pandas Series data = [10, 20, 40, 80, 100]

Create a Series using the Series() meth s = pd.Series(data)

Display the Series
print("Series: \n", s) # Datatype
print("\nSeries Datatype: ", s.dtype)

Output

1 40 80 3 100 dtype: int64 Series Datatype: int64

ndim

The pandas.series.ndim is used to return umber of dimensions of the Series.

y soo an evample to implement

10:44 | 6.8KB/s ්ර

ndim

The **pandas.series.ndim** is used to return the number of dimensions of the Series.

Let us now see an example to implement

the ndim attribute in Q <u>Python</u> Pand Men

import pandas **as** pd

Data to be stored in the Pandas Series
data = [10, 20, 40, 80, 100]

Create a Series using the Series() meth s = pd.Series(data)

Display the Series
print("Series: \n", s)

Dimensions print("\nSeries Dimensions: ", s.ndim)

Output

100

Series: 10 1 2 3 20 80

dtype: int64 Series Dimensions: 1

size

The pandas.series.size is used to return ımber of elements in the Pandas

Series

10:44 | 60.7KB/s ூ வி.பி இ 82)

Size The pandas.series.size is used to return

the number of elements in the Pandas Series.

Let us now see an example to implement the size attribute in Q <u>Python</u> Panda Menu

import pandas as pd

Data to be stored in the Pandas Series
data = [10, 20, 40, 80, 100]

Create a Series using the Series() meth
s = pd.Series(data)

Display the Series
print("Series: \n", s)

Return the number of elements in the Se
print("\nSeries Size: ", s.size)

Output

0

1

2

3

Series:

10

20

40

80

4 100 dtype: int64 Series Size: 5

name ar

andas.series.name is used to return

tne name of the Series in Pandas.

all all 🛜 📴 10:44 | 1.4KB/s © name

The **pandas.series.name** is used to return

the name of the Series in Pandas. Let us now see an example to implement

the name attribute in Q <u>Python</u> Pandas:

Menu import pandas as pd # Data to be stored in the Pandas Series data = [10, 20, 40, 80, 100]

Create a Series using the Series() meth
We have set the Series name using the n s = pd.Series(data, name ="MyNumberSeries # Display the Series print("Series: \n", s)

Return the name of the Series print("\nSeries Name: ", s.name)

Output

Series: 10 20 40 80 100 Name: MyNumberSeries, dtype: int64

Series Name: MyNumberSeries

hasnans

The pandas.series.hasnans attribute

ns True if NaNs are in the Pandas

Series.

The pandas.series.hasnans attribute

returns True if NaNs are in the Pandas Series.

Let us now see an example to implement the hasnans attribute in Q Python Men

Pandas:

```
import pandas as pd
import numpy as np
# Data to be stored in the Pandas Series
```

data = [10, 20, 40, 80, 100, np.NaN]
Create a Series using the Series() meth
s = pd.Series(data)

```
# Display the Series
print("Series: \n", s)
```

Check whether the Series has NaNs
print("\nDoes the Series has NaN? ", s.ha

Output

Series:

0 10.0 1 20.0 2 40.0 3 80.0 4 100.0 5 NaN dtype: float64

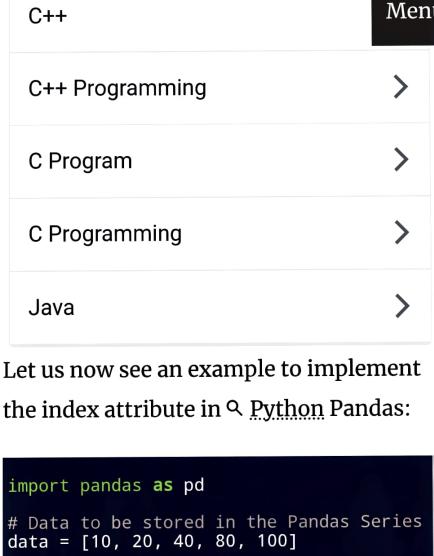

Does the Series has NaN? True

The **pandas.series.index** attribute is used

to display the index of the Pandas Series.
